Problem Set 4

Tate Mason

Question 1 - Hansen 7.17

Part A

Part B

Part C

Question 2 - Hansen 7.28

```r
library(haven)
library(dplyr)
```

```
Attaching package: 'dplyr'

The following objects are masked from 'package:stats':

    filter, lag

The following objects are masked from 'package:base':

    intersect, setdiff, setequal, union
```

1

```r
rm(list = ls())

dat <- read_dta('~/SchoolWork/Sem2/Metrics/PSets/PS3/cps09mar.dta')
sample <- (dat[,11]==1)&(dat[,2]==0)&(dat[,3]==1)
df <- dat[sample,]

y <- as.matrix(log(df[,5]/(df[,6]*df[,7])))
exp <- df[,1]-df[,4]-6
exp2 <- (exp^2)/100

x_df <- data.frame(
  education = df[,4],
  experience = exp,
  exp_squared = exp2,
  intercept = 1
)
x <- as.matrix(x_df)

xx <- t(x)%*%x
xy <- t(x)%*%y
beta <- solve(xx,xy)

fitted <- x %*% beta
resid <- y - fitted

n <- nrow(x)
k <- ncol(x)
xx_inv <- solve(t(x)%*%x)

df <- n-k

hc0 <- matrix(0, nrow=k, ncol=k)
for (i in 1:n) {
  xi <- matrix(x[i,], nrow=k)
  hc0 <- hc0 + resid[i]^2 * (xi %*% t(xi))
}
```

Part B

2

```
theta_hat <- beta[1]/(beta[2]+beta[3]/5)
cat("\nPart B: Estimated Theta")
```

Part B: Estimated Theta

```
print(theta_hat)
```

[1] 3.468335

Part C

```
gradient_g <- c(
  1/(beta[2] + beta[3]/5),
  -beta[1]/(beta[2]+beta[3]/5)^2,
  -beta[1]/(5*(beta[2]+beta[3]/5)^2),
  0
)

theta_se <- sqrt(t(gradient_g) %*% hc0 %*% gradient_g)
print(theta_se)
```

```
         [,1]
[1,] 121935.8
```

Part D

Part E

EQ 1

EQ 2

```r
b0 <- 0
b1 <- 1
n <- 100
sim <- function() {
  X1 <- rexp(n)
  e <- mixtools::rnormmix(n,lambda=c(0.5,0.5),mu=c(-1,2),sigma=c(1,1))
  Y <- b0 + b1*X1 + e
  x <- cbind(1,X1)
  xx <- t(x)%*%x
  xy <- t(x)%*%Y
  bhat <- solve(xx,xy)
  return(c(bhat[2]))
}
```

These results show that the average of $\hat{\beta}_1 \to \beta_1$ as n grows. The variance also approaches 0. This is consistent with what was derived in class, that as $n \to \infty$, we see the predicted approach the actual, and variance should be 0 as with sufficiently large n, there will be no variance in observations.

```r
run_mc <- function(n_sims = 1000) {
  mc_res <- sapply(1:n_sims, function(s) {
    sim()
  })
  cat("Mean b1:", mean(mc_res), "\n")
  cat("Variance of b1:", var(mc_res), "\n")
}
```

```r
run_mc()
```

```
Mean b1: 1.00064
Variance of b1: 0.03828634
```

```r
n <- 2
run_mc()
```

```
Mean b1: 20.36982
Variance of b1: 280954.1
```

```
n <- 10
run_mc()
```

```
Mean b1: 0.9765303
Variance of b1: 0.7344353
```

```
n <- 50
run_mc()
```

```
Mean b1: 1.001743
Variance of b1: 0.07827652
```

```
n <- 500
run_mc()
```

```
Mean b1: 0.9989494
Variance of b1: 0.006521762
```

As $n \to \infty$, the mean and variance get closer to the true values. This is a showcase of the WLLN.

EQ 3

Part A

```
b0 <- 0
b1 <- 1
num_sims <- 1000
alpha <- 0.05

sim_test <- function(n,b1_true, b1_null) {
  X <- rexp(n)
  e <- mixtools::rnormmix(n,lambda=c(0.5,0.5),mu=c(-2,2),sigma=c(1,1))
  Y <- b0+b1*X + e
  x <- cbind(1,X)
  xx <- t(x)%*%x
  xy <- t(x)%*%Y
```

```r
  bhat <- solve(xx,xy)
  b0_hat <- bhat[1]
  b1_hat <- bhat[2]

  yhat <- x %*% bhat
  ehat <- Y - yhat
